Summary

This report summarises data from the 2011 Northern Territory (NT) Midwives’ Collection. It includes population characteristics of mothers, maternal health status, antenatal information, conditions and procedures used in labour and childbirth as well as birth outcomes of all births that occurred in 2011. While the NT Midwives’ Collection contains information on both NT residents and interstate residents who gave birth in the NT, the focus of this report is NT residents who gave birth in the NT. Unless otherwise stated, the following key findings are for NT residents.

The primary purpose of the report is to inform and encourage professional discussion regarding the health of women and their babies. This report will assist policy makers and health planners to provide better services to the community. In addition, this report aims to provide feedback to midwives, Aboriginal Health Workers, community health nurses and medical practitioners involved with maternal and child health.

Key findings

- During 2011, there were 3,845 babies born to 3,792 NT mothers, 36% of whom were Indigenous. In addition there were 84 interstate mothers who gave birth to 84 babies in the NT. The total number of births in the NT for this year was 3,929 babies born to 3,876 mothers.
- Indigenous women had a higher total fertility rate (TFR) than that reported for all Australian women during the same period (2.21 and 1.89 births per woman respectively). The TFR of non-Indigenous women (1.90) was comparable with the national rate.
- The mean age of Indigenous mothers (24.8 years) was five years younger than that of non-Indigenous mothers (29.8 years). A fifth of Indigenous mothers (20%) were less than 20 years of age.
- Non-Indigenous mothers were almost three times more likely to be in the oldest age group (35 years and over) than Indigenous mothers (21% and 8% respectively).
- A greater proportion of Indigenous mothers (26%) had three or more previous births compared with non-Indigenous mothers (8%). Similarly, a smaller proportion of Indigenous than non-Indigenous mothers (31% and 45% respectively) gave birth to their first baby.
- Indigenous mothers were more likely to have insufficient antenatal care (no antenatal visit or attended less than four visits) compared with non-Indigenous mothers (13% and 1% respectively).
- Eighty-two per cent of non-Indigenous mothers attended their first antenatal visit during their first trimester of pregnancy compared with 50% of Indigenous mothers.
- Indigenous mothers were four times more likely to report smoking during the first 20 weeks of pregnancy compared with non-Indigenous mothers (51% and 12% respectively).
- Onset of labour was induced for a quarter (24%) of all NT mothers.
The majority of presentations were vertex (95%) while breech accounted for 4% and other presentations 1%.

Fifty-nine per cent of all NT mothers had a spontaneous vaginal delivery and 9% had an assisted vaginal delivery. Of the assisted vaginal deliveries, the majority (8%) were instrumental deliveries using forceps or ventouse (vacuum suction) and the remainder were vaginal breech (less than 1%).

Among those who gave birth vaginally, 38% had an intact perineum, while 48% had some degree of perineal laceration. The remainder had an episiotomy (13%) or a combination of episiotomy and tear (1%).

Almost a third (32%) of all NT mothers had a caesarean section. Indigenous mothers were more likely to undergo a caesarean section for emergency reasons (69%) than non-Indigenous mothers (50%).

The main reason for elective caesarean section births was a previous caesarean section (69%). The main reasons for emergency caesarean section births were failure to progress during labour (47%) and fetal distress (non-reassuring fetal status) (37%). Indigenous mothers were more likely to have an emergency caesarean section because of fetal distress than non-Indigenous mothers (43% and 33% respectively).

Over half of all NT mothers (57%) stayed in hospital for three days or less following birth.

Ten per cent of all NT live births were preterm (less than 37 weeks). The proportion of preterm babies born to Indigenous mothers was double that of preterm babies born to non-Indigenous mothers (16% and 7% respectively).

Ten per cent of all NT live births were low in birthweight (less than 2500 grams). The proportion of low birthweight babies born to Indigenous mothers was more than double that of low birthweight babies born to non-Indigenous mothers (16% and 6% respectively).

A small percentage of all NT full term (37 weeks and over) singleton live births were of low birthweight; 6% of those born to Indigenous mothers and 1% to non-Indigenous mothers.

By five minutes after birth, 2% per cent of NT liveborn babies had an Apgar score below seven.

Twenty-two per cent of all NT live births received some form of resuscitation, excluding tactile stimulation. Resuscitation rates were higher among Indigenous compared with non-Indigenous liveborn babies (27% and 20% respectively).

There were 53 perinatal deaths comprising 27 fetal deaths (stillbirths) and 26 neonatal deaths. The overall Indigenous perinatal death rate was over two times that of the non-Indigenous rate (23.4 and 8.5 deaths per 1000 births respectively).
Introduction

This report summarises data from the 2011 Northern Territory (NT) Midwives’ Collection. It includes population characteristics of mothers, maternal health status, antenatal information, conditions and procedures used in labour and childbirth as well as birth outcomes for all births that occurred in 2011. The trend tables show changes over time for key demographic and obstetric indicators and birth outcomes over the period 1997–2011.

The primary purpose of the report is to inform and encourage professional discussion regarding the health of women and their babies. This report will assist policy makers and health planners to provide better services to the community. In addition, this report aims to provide feedback to midwives, Aboriginal Health Workers, community health nurses and medical practitioners involved with maternal and child health.

Information presented in this report

The NT Midwives’ Collection contains information on both NT residents and interstate residents who gave birth in the NT. However, the focus of this report is NT residents who gave birth in the NT. Unless specified, mothers usually residing interstate and births to them were omitted from the statistical tables.

Information on Territory women who gave birth interstate is not collected in the NT Midwives’ Collection and is beyond the scope of this report. Australia’s Mothers and Babies 2011 report published estimated numbers of NT women who gave birth interstate. It was estimated, in 2011, that up to 65 NT women gave birth interstate, predominantly in South Australia (31 births) and Queensland (20 births) with the balance spread between all remaining Australian jurisdictions, with the exception of Tasmania. Indigenous status was not available for interstate births to NT women.

In this report the maternal Indigenous status was used during analysis of both mother and baby information. For information on labour and childbirth in the Mothers’ section of this report, the data of the first birth were used for mothers with multiple births in one pregnancy.

A brief description of the results is presented in the next chapter followed by a comprehensive presentation of the data in a series of tables. Most tables are presented with information for all women as well as separately by Indigenous status and, in some, place of mother’s usual residence (for NT mothers). Place of mother’s usual residence is classified into health service districts, and into urban/rural-remote areas. The urban area includes Darwin Urban and Alice Springs Urban districts and the towns of Katherine, Tennant Creek and Nhulunbuy; the rural-remote area covers the balance of the NT.

Data sources

Northern Territory Midwives’ Collection

The NT Midwives’ Collection is a population-based census of all births that occurred in the NT, including births in public and private hospitals, planned home births, births in community health centres, and other non-hospital births. All live births and fetal deaths (stillbirths) of at least 20 weeks gestation or with a birthweight of at least 400 grams are included.
The NT Midwives’ Collection contains information about population characteristics of the mother, antenatal care, maternal health, the pregnancy, labour and childbirth, and perinatal health.

In 2011 the majority of information about the births was captured directly in electronic format. In the public sector, midwives enter data shortly after the birth of a baby via the Birthing Suite Module of CareSys, the Hospital Information System. This normally covers births that occurred in public hospitals and births before arrival (BBAs). Births in Darwin Private Hospital (DPH) and planned home births are entered via the internet site of the NT Midwives’ Collection. Births that occurred in health centres, which did not involve being admitted to hospital, are submitted in paper form and then entered by the perinatal data manager onto the intranet site.

In producing this report, data from the Midwives’ Collection were downloaded in unit record form from Business Objects and transferred into a statistical program. The data went through further validation and corrections were transferred back to the Midwives’ Collection systems.

NT Perinatal Death Register

The Health Gains Planning Branch of the Department of Health has maintained information on deaths of babies up to one year of age since 1986. The primary sources for the register are the monthly death list from the NT Births, Deaths and Marriage Registry for neonatal deaths and the NT Midwives’ Collection for fetal deaths. The hospital morbidity dataset is also used as another source of data.

Data limitations

Several data items in the Midwives’ Collection, notably antenatal information including parity, previous caesareans, smoking and alcohol use during pregnancy, maternal medical conditions and pregnancy complications as well as indications for caesarean section are incomplete or low in accuracy. This is primarily due to the indirect data collection method and the lack of a validating process.

The treatment of ‘not stated’ data requires careful consideration depending upon the cause of the missing data. For example data may be missing due to refusal of clients to answer a question or may simply be missing completely at random (MCAR). While there are no hard and fast rules as to how ‘not stated’ data are reported, as a default position the Australian Institute of Health and Welfare (AIHW) recommends that ‘not stated’ are shown in tables as numbers and excluded from the calculation of percentage distributions. This methodology assumes that the ‘stated’ and the ‘not stated’ share the same distribution (unpublished guidelines, AIHW, 2008).

In the Mothers and Babies 2003 report, the Health Gains Planning Branch commenced using the AIHW default position and ‘not stated’ data were excluded from calculation of percentage distributions. This approach differs from reports compiled prior to the 2003 report. In these reports, ‘not stated’ data were included as a percentage of the total in each table.

The effect of our change in approach is that the proportional distribution for certain data items, particularly alcohol consumption and/or smoking during pregnancy, is now markedly higher than previously reported. Comparative analyses involving reports published from 2003 and those published prior to 2003 will need to take this methodological change into account.
The data used in this report are limited to the health information available at the time of data entry. In instances where an antenatal record is incomplete or missing, the midwife entering information into the Birthing Suite Module of CareSys or the internet site of the NT Midwives’ Collection is limited to the details at hand. Key antenatal indicators such as visit dates and health behaviours are most likely to be affected as this information is only recorded on antenatal records.

For some medical conditions, procedures and complications related to labour and childbirth, the data in the Midwives’ Collection are sometimes different from the information recorded in the main hospital data system. This is due to the different data coding and entry methods with midwives responsible for data in the Midwives’ Collection and medical coders responsible for data entry to the main hospital data system.

Information such as mother’s post-partum complications and baby’s further health outcomes are not collected in the NT Midwives’ Collection because they are recorded only after mothers and babies have left the birthing suite.

The denominator population used to calculate fertility rates is the 2011 NT Estimated Resident Population based on the 2011 ABS Census of Population and Housing.

Because the NT population is small, when data are disaggregated by Indigenous status or region the numbers being reported can be very small. When small numbers are used, seemingly large differences can be seen when percentage rates are calculated, even if the difference is only one or two births. When there is a risk of attributes about an individual being disclosed due to a small number of cases, relevant cells or tables are suppressed. In 2011 there were a total of four births at Tennant Creek Hospital and as a result a hospital profile has not been presented in Appendix 1.

A further issue with data disaggregated by region for the Indigenous population is difficulties individuals have identifying one usual place of residence. This is particularly true for pregnant women who have to travel to and stay in town from 36 weeks gestation to be close to a hospital when they give birth. The place they are staying in town could thus be recorded as their usual place of residence and not the community they have travelled from. A recent audit of NT hospital demographic data found 91% congruence between hospital records of patients’ usual health district of residence and the health district people identified as their usual place of residence when asked in an interview.
Mothers and babies of the Northern Territory

Mothers

Place of residence

In 2011, a total of 3,876 mothers gave birth to 3,929 babies in the NT, of which 3,901 were live births. Among all babies born in the NT, most were born to mothers who were resident in the NT. There were 84 mothers from interstate who gave birth to 84 babies (2% of all babies born in the NT).

Indigenous mothers comprised 36% of all NT mothers in 2011. This is higher than the share of the NT female population of child-bearing age (i.e. 15-49 years) made up of Indigenous women. In 2011, Indigenous women comprised 31% of all NT women of child-bearing age (Appendix 3).

Most NT non-Indigenous mothers were living in urban areas (96%), which include Darwin Urban and Alice Springs Urban districts and the towns of Katherine, Tennant Creek and Nhulunbuy. In contrast, Indigenous mothers were predominantly from rural and remote areas (64%).

Fertility rate

The total fertility rate (TFR) for the NT was 2.08 live births per woman in 2011, which is below the replacement rate of 2.1 births per woman and was higher than the 1.89 births per woman for the whole of Australia in the same period. Non-Indigenous NT women had a lower TFR than Indigenous women (1.90 and 2.21 births per woman respectively).

This pattern of higher TFRs for Indigenous women compared with non-Indigenous women was seen in both urban and rural-remote areas and in all districts with the exception of Darwin Urban and East Arnhem. Katherine and Barkley districts had the highest TFR for all NT women, whilst Alice Springs Rural had the lowest (2.7 and 1.8 respectively).

The age-specific fertility rates show differences in the age of child-bearing between the Indigenous and non-Indigenous populations. The fertility rate in the youngest age group (less than 20 years of age) was over four times higher for Indigenous women compared with non-Indigenous women of the same age (81.6 and 17.8 births per 1,000 women respectively). Conversely, the fertility rate of the 35 and older age group was higher for non-Indigenous mothers compared with Indigenous mothers (28.2 and 15.9 respectively), despite a lower overall fertility rate.

Maternal age

The mean age of Indigenous mothers was 24.8 years, which was five years younger than the mean age of 29.8 years for non-Indigenous mothers. This difference was due to the age profile of mothers. Fifty-four per cent of Indigenous mothers were aged less than 25 years, whereas just over half of non-Indigenous mothers were 30 years or older. A fifth (20%) of Indigenous mothers were less than 20 years of age at the time of giving birth, almost seven times higher than the 3% of non-Indigenous mothers. A more
marked difference was seen among mothers aged less than 18 years with 9% of all Indigenous mothers being in this age group, compared with only 0.7% of non-Indigenous mothers. In contrast, non-Indigenous mothers were almost three times more likely to be in the oldest age group (35 years and over) than Indigenous mothers (21% and 8% respectively). This pattern of markedly earlier childbearing among Indigenous mothers was seen in all health districts and in both urban and rural-remote areas.

Indigenous mothers in Barkly were more likely to have their children below age 20 (30%) compared with Indigenous mothers in other health districts where the proportion of young mothers (less than 20 years) was between 11% and 26%. Across the NT the proportion of young Indigenous mothers was lower in urban areas (16%) than in rural-remote areas (23%).

Parity

Among those women with parity recorded, the majority had given birth at least once before. Nearly half (46%) had one or two previous births and 14% had three or more previous births. Forty per cent of women gave birth to their first child. First-time mothers were proportionally higher among non-Indigenous mothers (45%) than Indigenous mothers (31%). Similarly, proportionally more Indigenous women than non-Indigenous had three or more previous births (26% and 8% respectively).

The difference in maternal age between Indigenous and non-Indigenous women was more pronounced among first-time mothers for whom there was an eight year difference in the mean age of birth (20 and 28 years respectively). The majority of non-Indigenous first-time mothers were aged 25 years or older (72%), whereas just over half (52%) of first-time Indigenous mothers were less than 20 years of age, and many were aged below 18 years of age (26%).

Antenatal care

The vast majority of mothers had information on antenatal visits recorded. In just over 2% of records the date of first visit or frequency of visits were not recorded. The World Health Organisation classifies less than four antenatal visits during the whole pregnancy to be insufficient. Among mothers for whom information was collected, Indigenous mothers in the NT were more likely to have insufficient antenatal care documented (no antenatal visit or attended less than four visits) compared with non-Indigenous mothers (13% and 1% respectively). Indigenous mothers living in urban areas were slightly more likely to have insufficient antenatal care compared with their counterparts in rural and remote areas (15% and 12% respectively).

It is important for maternal and fetal health for women to have their first antenatal visit within the first trimester of pregnancy. In this report, first trimester is defined as gestational age less than fourteen weeks from conception. This definition is consistent with the National Indigenous Reform Agreement definition endorsed onto Australia’s online repository for metadata standards (METeOR) in June 2013 and differs from NT perinatal reports published prior to 2013. In these reports, first trimester was defined as less than thirteen weeks.

In this report gestational age at the first antenatal visit was derived from three sources to determine the lowest valid gestational age. These sources were the date of the first antenatal visit, the date of the first ultrasound or the recorded gestational age at the time of the first ultrasound.

Compared with non-Indigenous mothers, Indigenous mothers were more likely to attend their first antenatal visit later in the pregnancy. Among those mothers who
attended at least one antenatal visit and had a record of the time of their first visit, 82% of non-Indigenous mothers attended their first visit during the first trimester of pregnancy. This proportion was much less for Indigenous mothers (50%). The proportion of Indigenous women attending a first antenatal visit in the first trimester was higher in urban areas than in rural-remote (56% and 46% respectively). Among non-Indigenous women, the proportion attending an antenatal visit in the first trimester was slightly higher in urban areas compared with remote (82% and 79% respectively).

**Alcohol consumption during pregnancy**

Self-reported alcohol consumption during pregnancy is collected at the first antenatal visit and again at around 36 weeks gestation. Although the collection of this indicator has improved in recent years the proportion of missing data remains sizeable. In this report 8% of alcohol consumption data were missing at the first visit and 18% at 36 weeks. Missing data for alcohol consumption was more prevalent among the antenatal records of Indigenous mothers than non-Indigenous mothers. The prevalence of alcohol consumption reported below was calculated after removing missing data.

At first antenatal visit, 6% of all NT mothers reported drinking alcohol during pregnancy. The prevalence of alcohol consumption was higher in Indigenous mothers (13% at the first visit and 7% at 36 weeks gestation) than non-Indigenous mothers (3% and 1%, respectively).

**Smoking status during pregnancy**

Smoking status during pregnancy is self-reported as having smoked during the first 20 weeks gestation and after 20 weeks gestation. These variables were introduced into the NT Midwives’ Collection to ensure consistency with the method of collecting smoking information in the National Minimum Dataset. Using this method, the proportion of data with missing smoking status was 2% for the first 20 weeks of gestation and 10% for post 20 weeks gestation. Similar to alcohol consumption, the missing data for smoking status was more prevalent among the antenatal records of Indigenous mothers than non-Indigenous mothers. The prevalence of smoking during pregnancy reported below was calculated by removing missing data from the denominator.

Twenty-five per cent of NT mothers reported smoking during the first 20 weeks of pregnancy, a rate much higher than alcohol consumption. Indigenous mothers were four times more likely than non-Indigenous mothers to report smoking during the first 20 weeks (51% and 12% respectively). By post 20 weeks gestation, smoking prevalence dropped slightly for all mothers, although Indigenous mothers were still almost five times more likely to report smoking compared with non-Indigenous mothers (48% and 10% respectively). For Indigenous mothers, smoking prevalence during the first 20 weeks was comparable between urban and rural-remote areas (50% and 51% respectively). Among non-Indigenous mothers, those residing in rural-remote areas were twice as likely to report smoking during the first 20 weeks compared with their urban counterparts (21% and 11% respectively).

Among Indigenous mothers, those mothers living in Alice Springs Rural district had notably lower smoking rates than other districts (although smoking levels were still high with almost one quarter of mothers smoking during the first 20 weeks). This pattern of lower smoking in Alice Springs Rural is consistent with data from previous years and may be related to the local practice of chewing tobacco (pituri) in the region.11
Birth facility

Nearly all NT births occurred in a hospital (97%). The majority of hospital births took place at one of the five public hospitals (81%) and the rest were in DPH, the only private hospital in the NT. Almost all mothers who gave birth in DPH were non-Indigenous (98%).

A small proportion of mothers (1%) had a planned homebirth and all were non-Indigenous. Four per cent of Indigenous mothers and less than 1% of non-Indigenous mothers had an unplanned non-hospital birth. Unplanned non-hospital births include births that occurred in either health centres, in transit to hospitals or in unintended locations, including unplanned births in the home. Health centres were the most common place for non-hospital births for Indigenous mothers. Darwin Rural health district had the largest proportion (7%) of non-hospital births, most of which occurred in health centres.

Onset of labour and induction of labour

Spontaneous onset of labour occurred for 60% of all mothers; a quarter of mothers (24%) had induced labour and 16% had no labour. Non-Indigenous mothers were less likely to have spontaneous onset of labour than Indigenous mothers (57% and 65% respectively) but slightly more likely to have induction to initiate the labour or have no labour. Indigenous mothers were more likely to be administered prostaglandins for induction of labour than non-Indigenous mothers (44% and 38% respectively).

Presentation and method of birth

Of all NT mothers giving birth in 2011, 59% had a spontaneous vaginal delivery (SVD). Indigenous mothers were more likely to have a SVD than non-Indigenous mothers (64% and 57% respectively). Almost a third (32%) of births were performed by caesarean section. Non-Indigenous mothers were more likely to have a caesarean section than Indigenous mothers (33% and 30% respectively). Among all hospitals in the NT, DPH had the highest proportion of caesarean section births (47%) and the lowest proportion of spontaneous vaginal births (42%).

Instrumental deliveries using forceps or ventouse (vacuum suction) in childbirth accounted for 8% of births and were more common among non-Indigenous mothers (10%) than Indigenous mothers (6%). Vaginal breech accounted for less than 1% of all births.

The majority of presentations were vertex (95%) while breech accounted for 4% and other presentations 1%. Caesarean section was the most common birth method for breech presentations, except for very preterm births (less than 28 weeks) which were mostly delivered vaginally.

Among mothers who had a caesarean section, Indigenous mothers were much more likely to undergo the procedure for emergency reasons (69%) compared with non-Indigenous mothers (50%). The primary reason for elective caesarean section births was previous caesarean section (69%). The main reasons for emergency caesarean section included: failure to progress during labour (47%), fetal distress (non-reassuring fetal status) (37%) and malpresentation (9%). Indigenous mothers were more likely to have an emergency caesarean section because of fetal distress than non-Indigenous mothers (43% and 33% respectively), whereas failure to progress was a more common indicator for emergency caesareans among non-Indigenous mothers compared with Indigenous mothers (51% and 41% respectively).
Analgesia for labour and anaesthesia for childbirth

The majority of mothers who had spontaneous or induced onset of labour used some form of analgesia (78%). Analgesia use was slightly higher among non-Indigenous mothers than Indigenous mothers (80% and 76% respectively).

Anaesthesia was applied in the vast majority of operative births, including births using forceps or ventouse or via caesarean section. Non-Indigenous women were more likely than Indigenous women to have an epidural or caudal anaesthesia (24% and 17% respectively). By contrast, there was higher use of spinal anaesthesia among Indigenous women than non-Indigenous women (64% and 59% respectively). General anaesthesia was administered for 10% of Indigenous women having operative births and 6% of non-Indigenous women.

Complications due to pregnancy and/or childbirth

This report presents information on a selection of pregnancy and/or childbirth complications. Half of all NT mothers (51%) experienced one of these complications. Indigenous mothers were more likely to have a complication than non-Indigenous mothers (59% and 47% respectively). Post-partum haemorrhage was the most common complication for Indigenous mothers (17%) and fetal distress for non-Indigenous mothers (13%). Indigenous mothers had higher rates of gestational diabetes mellitus and pre-existing diabetes mellitus (9% and 4% respectively) compared with non-Indigenous mothers (6% and less than one per cent respectively). Pre-eclampsia was higher among Indigenous mothers compared with non-Indigenous mothers (6% and 2% respectively).

Perineal status

Thirty-eight per cent of all mothers who gave birth vaginally had an intact perineum after childbirth, while 48% had some degree of perineal laceration. A small proportion (3%) had a third or fourth degree tear. Episiotomy was performed on 13% of women. Indigenous mothers were more likely than non-Indigenous mothers to have an intact perineum (47% and 33% respectively).

Postnatal hospital stay

The majority of mothers who gave birth in hospital also stayed in hospital following the birth for one day or more (93%). Most stays were for less than one week and only 4% of women stayed for eight or more days. The average length of stay was 3.4 days. Indigenous mothers were more likely than non-Indigenous mothers to have a hospital stay and more likely to stay for eight or more days. The mean length of stay for emergency caesarean section was 1.5 days longer for Indigenous mothers compared with non-Indigenous mothers. The overall average length of stay for all birth methods was only slightly longer among Indigenous mothers compared with non-Indigenous mothers (3.9 days and 3.2 days respectively).
Babies

Birth status
In 2011, a total of 3,929 babies were born in the NT. Of these, 84 were born to mothers who were not NT residents. Of the 3,845 babies born to NT mothers, 27 were fetal deaths and 3,818 were live births. The proportion Indigenous fetal deaths (1.2%) was three times that of non-Indigenous fetal deaths (0.4%). Most fetal deaths (70%) had extremely low birthweight of less than 1000 grams. Similarly, two thirds (67%) were very preterm, being born before 28 weeks gestation.

Plurality
There were 53 twin births in 2011. Multiple births were comparable among Indigenous and non-Indigenous mothers (1.4% respectively).

Preterm and low birthweight liveborn babies
Altogether there were 397 (10%) preterm live births (gestational age less than 37 weeks). Proportionally there were twice as many preterm babies born to Indigenous mothers (16%) than to non-Indigenous mothers (7%). Twenty one of the 31 babies in the very preterm category (less than 28 weeks gestation) were born to Indigenous mothers.

Of all liveborn babies, 10% were low birthweight (less than 2500 grams). Babies of Indigenous mothers (16%) were more than twice as likely to have a low birthweight as babies of non-Indigenous mothers (6%). The difference was also seen in very low birthweight babies (less than 1500 grams), with 3% of babies born to Indigenous mothers in this category compared with 1% of babies born to non-Indigenous mothers. In each district, Indigenous mothers were more likely to have low birthweight babies than non-Indigenous mothers.

Among full term (37 weeks and over) singleton liveborn babies, 6% of those born to Indigenous mothers were of low birthweight compared with 1% born to non-Indigenous mothers. For those born preterm (28-36 weeks gestation) the proportion of babies at least 2500 grams in weight was comparable between Indigenous and non-Indigenous mothers (42% and 43% respectively).

Apgar scores
An Apgar score is a clinical indicator of the condition of the baby at birth. Five physical signs are each assigned a score of 0, 1 or 2, and the highest total Apgar score is 10. A score of 7-10 indicates a healthy baby. By five minutes after birth 2% of all NT liveborn babies had an Apgar score below seven, and for Indigenous and non-Indigenous babies the proportions were 3.3% and 1.5% respectively.

Resuscitation of liveborn babies
Twenty-two per cent of babies born alive received some form of resuscitation, excluding tactile stimulation. Resuscitation rates were higher among Indigenous compared with non-Indigenous liveborn babies (27% and 20% respectively). The most common methods of resuscitation were intermittent positive pressure ventilation (IPPV) (9%), suction only (6%) and facial oxygen only (5%). Methods such as intubation or external cardiac massage and ventilation (1%) were uncommon.
Perinatal mortality

Perinatal mortality includes fetal deaths (stillbirths) and neonatal deaths. Neonatal mortality refers to a death of a liveborn baby within 28 days of birth. In 2011 there were 53 perinatal deaths in the NT comprising 27 fetal deaths and 26 neonatal deaths. There were a higher number of fetal deaths to Indigenous mothers compared with non-Indigenous mothers (16 and 11 respectively). For the 26 neonatal deaths, 16 were Indigenous and 10 non-Indigenous. The overall Indigenous perinatal death rate was over two times that of the non-Indigenous rate (23.4 and 8.5 deaths per 1000 births respectively).

<td>100.0</td>
</tr>
</tbody>
</table>

Notes:
1. Resuscitation methods exclude tactile stimulation.
2. IPPV stands for intermittent positive pressure ventilation.
3. ECM stands for external cardiac massage.
4. Other resuscitation includes stimulation methods such as intramuscular treatment, continuous positive airway pressure (CPAP). 
5. The Indigenous status of the mothers of three babies was unknown. The babies of these mothers were only included in the count of All NT.

### Table 51. Numbers and rates of fetal deaths, neonatal deaths and perinatal deaths, by Indigenous status, NT babies, 2011

<table>
<thead>
<tr>

<td>Perinatal deaths</td>
<td>32</td>
<td>23.4</td>
<td>21</td>
<td>8.5</td>
<td>53</td>
<td>13.8</td>
</tr>
</tbody>
</table>

Notes:
1. Rate of fetal deaths or perinatal deaths is the number of deaths per 1000 total births; rate of neonatal deaths is the number of deaths per 1000 live births.
2. Fetal deaths are by maternal Indigenous status and neonatal deaths are by Indigenous status of the babies. Perinatal deaths are therefore a mix of maternal and baby’s Indigenous status.
Appendices

Appendix 1. Hospital profiles

The profile table of each hospital includes all births that occurred in that hospital in 2011, among mothers who were either NT residents or from interstate.

</table>

Notes:
(1) This table includes all births that occurred in ASH in 2011. An additional 12 births occurred before arrival at hospital and are reported in the Appendix 1 table for non-hospital births.
(2) Not stated category is not presented and so the total may differ from the sum of the variable components.
(3) Diabetes in pregnancy includes gestational diabetes mellitus and pre-existing diabetes mellitus.

</table>

**Notes:**
1. This table comprises all births that occurred out of hospital in 2011, including planned home births, births in health centres and other locations such as in transit to hospital or unintended places.
2. Not stated category is not presented and so the total may differ from the sum of the variable components.
3. Diabetes in pregnancy includes gestational diabetes mellitus and pre-existing diabetes mellitus.

The following trends tables summarise key indicators over time by Indigenous status. Numbers are provided in tables A.1, B.1 and C.1. Proportions are provided in tables A.2, B.2 and C.2.

Glossary

This section provides definitions for a selection of key perinatal terms. For a more comprehensive glossary please see Australia’s Mothers and Babies 2011.¹

**Age-specific fertility rate:** The number of births per individual within a specific age interval during a specified time.

**Apgar score:** numerical score used to indicate the baby’s condition at one minute and five minutes after birth. A score of 0, 1 or 2 is given for each of five characteristics; heart rate, breathing, colour, muscle tone and reflex irritability, and the total score is between 0 and 10.

**Augmentation of labour:** intervention after the onset of labour to assist the progress of labour.

**Birth status:** status of the baby immediately after birth.

**Birthweight:** the first weight of a baby (stillborn or liveborn) obtained after birth, measured to the nearest 5 grams and usually obtained within one hour of birth. Low weight births can be classified at the following levels:

- Low birthweight: less than 2500 grams
- Very low birthweight: less than 1500 grams
- Extremely low birthweight: less than 1000 grams.

**Born before arrival:** a term used for deliveries which occur before reaching the hospital.

**Caesarean section:** operative birth by surgical incision through the abdominal wall and uterus. It is often divided into two sub-categories:

- Elective caesarean section: A caesarean section (planned or unplanned) performed before the onset of labour, usually due to health risks to the mother or baby.
- Emergency caesarean section: A caesarean section performed after the onset of labour, whether or not the onset of labour was spontaneous.

**Epidural/Caudal:** Analgesia or anaesthesia produced by injection of a local anaesthetic into the epidural space of the spinal cord or caudal canal.

**Episiotomy:** an incision of the perineum and vagina to enlarge the vulval orifice.

**Fetal death (Stillbirth):** death prior to the complete expulsion or extraction from its mother of a product of conception of 20 or more completed weeks of gestation or of 400 grams or more birthweight. The death is indicated by the fact that after such separation the fetus does not breathe or show any other evidence of life, such as beating of the heart, pulsation of the umbilical cord, or definite movement of voluntary muscles.

**Fetal death rate:** the number of fetal deaths (stillbirths) in a year per 1000 total births in that same year.

**Forceps:** assisted birth using a metallic obstetric instrument.
First-time mother: also called primiparous mother, refers to a woman who is giving birth for the first time.

Gestational age: the duration of a pregnancy in completed weeks, calculated from the date of the first day of women’s last menstrual period to her baby’s date of birth. Each birth can be categorized, according to fetal gestational age, into:
- Preterm baby: A baby born before 37 completed weeks of gestation;
- Term baby: A baby born from 37 completed weeks up to 41 completed weeks of gestation; or
- Post-term baby: A baby born after 41 completed weeks of gestation.

Induction of labour: intervention to stimulate the onset of labour.

Instrumental birth: includes vaginal birth by forceps or ventouse (vacuum extraction).

Labour: the process by which the products of conception are expelled from the uterus via the birth canal.

Live birth: the complete expulsion or extraction from its mother of a baby, irrespective of duration of pregnancy, which after separation shows signs of life.

Maternal age: mother’s age in completed years at the birth of her baby.

Mother’s length of postnatal hospital stay: number of days between date of baby’s birth and separation date of the mother (from the hospital where birth occurred). The interval is calculated by subtracting the date of baby’s birth from the date of separation.

Neonatal death: death of a liveborn baby within 28 days of birth.

Neonatal death rate: the neonatal deaths in a year per 1000 live births in that same year.

Parity: number of previous pregnancies resulting in live births or stillbirths, excluding the current pregnancy.

Perinatal death: a fetal or neonatal death.

Perinatal death rate: the sum of fetal deaths (stillbirths) and neonatal deaths in a year per 1000 total births in that same year.

Perineal status: status of the perineum after the birth. It may involve surgical suturing of perineal laceration (tear) or episiotomy incision.

Plurality: the number of babies resulting from a pregnancy. According to plurality a pregnancy can be defined as either
- Singleton birth: with one baby; or
- Multiple birth: with more than one baby.

Presentation at birth: presenting part of the fetus at birth.

Pudendal: local anaesthetic to block the pudendal nerves.
Resuscitation of baby: active measures taken shortly after birth to assist the baby’s ventilation and heartbeat, or to treat depressed respiratory effort and to correct metabolic disturbances.

Spontaneous vaginal: birth without intervention in which the baby’s head is the presenting part.

Teenage mother: mother aged less than 20 years at the birth of her baby.

Total fertility rate: a hypothetical measure of the number of live births a woman would have if, throughout her reproductive years, she had children at the age-specific rates that were observed in any one year.

Ventouse (Vacuum extraction): assisted birth using a suction cap applied to the baby’s head.

Vaginal breech: vaginal birth in which the baby’s buttocks or lower limbs are the presenting parts.
